A: I believe you can download the whole bundle from here Q: Python: Multiple async calls inside a nested async function I'm writing a web service that will receive a query (a list of ids), and for each of those ids, make an API call. The problem is that I need the final (and only) result to be received as a result. However, I must call the API for each of the ids, which means that the service will be called until all ids have been processed. I need to use async because I can't call an external API, and I read that this is the most efficient way to do it: async def process_ids(ids): results = [] urls = [] for id in ids: urls.append(url + 'api.com/call') results.append(await fetch_url(urls[-1])) return results There might be more than one id, so, if a client sends for example 2 ids, the service will be called 2x as many times as for one id. If it's because of the way I'm using the list, I'd be open to any suggestions (am I using it wrong?). Also, I'd need to return the final (so the last item in results) value as a result. A: It looks like you don't need any async and await here, rather you can just make a list of urls and call them in a loop, for example: async def process_ids(ids): results = [] urls = [] for id in ids: urls.append(url + 'api.com/call') results.append(await fetch_url(urls[-1])) return results Something like this. You don't need to return anything then, as you need the final value, so just make a callback that'll take the result from the last async call. Q: Determine if the function is smooth Let $f: \mathbb{R}^
